Preface DACH Capital Market Study

Dear business partners and friends of ValueTrust,

We are pleased to release our thirteenth edition of the ValueTrust DACH¹) Capital Market Study powered by finexperf and W Vienna. The study was carried out by ValueTrust in cooperation with finexperf and the Institute of Accounting and Auditing at the W Vienna. With this study, we provide a data compilation of the capital market parameters which enable an enterprise valuation in Germany, Austria and Switzerland. It has the purpose to serve as an assistant and data source as well as to show trends in the analyzed parameters.

In this study, we analyze the relevant parameters to calculate the costs of capital based on the Capital Asset Pricing Model (risk-free rate, market risk premium and beta). Additionally, we determine implied as well as historical market and sector returns. Moreover, this study includes capital structure-adjusted implied sector returns, which serve as an indicator for the unlevered cost of equity. The relevered cost of equity can be calculated by adapting the company specific debt situation to the unlevered cost of equity. This procedure serves as an alternative to the CAPM.

Furthermore, we provide an analysis of empirical (ex-post) costs of equity in the form of **total shareholder returns** which consist of capital gains and dividends. The total shareholder returns can be used as a plausibility check of the implied (exante) returns. Lastly, **trading multiples** frame the end of this study.

We examine the before mentioned parameters for the **German**, **Austrian** and **Swiss capital markets** (in form of the CDAX²), WBI³) and SPI⁴). These indices have been merged into **twelve finexpert sector indices** (so-called "super sectors") Banking, Insurance, Financial Services, Consumer Service, Consumer Goods, Pharma & Healthcare, Information Technology, Telecommunication, Utilities, Basic Materials, Industrials and Real Estate.

Historical data has been compiled between the reference dates June 30, 2017 and June 30, 2023 and will be updated semi-annually, with the objective that historical, as well as current data, can be consulted at the same time. Hence, we can understand changes over time, which allows us to track the performance of all three capital markets. Additionally, further knowledge and information for financial decision making is provided at <u>www.finexpert.info</u>.

- Nominated expert in valuation disputes

Disclaimer DACH Capital Market Study

This study presents an empirical analysis which serves the purpose of illustrating the cost of capital of Germany's, Austria's, and Switzerland's capital markets. Nevertheless, the available information and the corresponding exemplifications do not allow for a complete presentation of a proper derivation of costs of capital. Furthermore, the market participant must consider that the company specific costs of capital can vary widely due to individual corporate circumstances.

The listed information is not specific to anyone and consequently, it cannot be directed to an individual or juristic person. Although we are always endeavoured to present information that is reliable, accurate, and current, we cannot guarantee that the data is applicable to valuation in the present as well as in the future. The same applies to our underlying data from the data provider S&P Capital IQ.

We recommend a self-contained, technical, and detailed analysis of the specific situation and we dissuade from acting solely based on the information provided.

ValueTrust and its co-authors do not assume any liability for the up-to-datedness, completeness or accuracy of this study or its contents.

Cost of equity per sector according to four different methodologies

Executive summary (1/2)

Sectors		Implied levered cost of equity	Levered cost of equity (CAPM) ¹⁾	1 / PE-ratio (1yf)	Total shareholder return (Ø 6y) ²⁾
	Banking	11.0%	8.5%	9.4%	5.3%
	Insurance	10.4%	9.6%	8.5%	11.9%
	Financial Services	7.5%	10.6%	6.5%	12.8%
	Consumer Service	6.2%	10.4%	4.7%	20.7%
	Consumer Goods	9.5%	11.0%	6.1%	12.2%
	Pharma & Healthcare	7.2%	10.3%	4.5%	11.5%

1. Based on 2-year sector beta, risk-free rate of 2.43% and implied market risk premium of 7.6% for the German market 2. Total shareholder returns can be viewed as historic, realized cost of equity. However, it has to be considered that total

shareholder returns vary widely, depending on the relevant time period

Cost of equity per sector according to four different methodologies

Executive summary (2/2)

Sectors		Implied levered cost of equity	Levered cost of equity (CAPM) ¹⁾	1 / PE-ratio (1yf)	Total shareholder return (Ø 6y) ²⁾
	Information Technology	6.4%	11.2%	5.5%	17.7%
	Telecommunication	8.7%	8.0%	6.1%	6.6%
	Utilities	7.4%	8.0%	7.7%	16.1%
	Basic Materials	10.0%	10.9%	8.3%	6.9%
	Industrials	7.5%	11.9%	6.2%	15.0%
	Real Estate	7.0%	8.7%	4.8%	5.2%

1. Based on 2-year sector beta, risk-free rate of 2.43% and implied market risk premium of 7.6% for the German market

2. Total shareholder returns can be viewed as historic, realized cost of equity. However, it has to be considered that total

shareholder returns vary widely, depending on the relevant time period

Background & approach

Risk-free rate

The **risk-free rate** is a return available on a security that the market generally regards as free of default risk. It serves as an input parameter for the **CAPM** and is used to determine the risk-adequate cost of capital.

The risk-free rate is a yield, which is obtained from **long-term government bonds** of countries with top notch ratings. By using interest rate data of different maturities, a **yield curve** can be estimated for fictitious zero-coupon bonds (spot rates) for a period of up to 30 years. Therefore, the German Central Bank (Deutsche Bundesbank) and the Swiss National Bank (Schweizer Nationalbank) publish – on a daily basis – the parameters needed to determine the yield curve using the **Svensson method**. Based on the respective yield curve, a **uniform risk-free rate** is derived under the assumption of present value equivalence to an infinite time horizon.

The **German bonds** are internationally classified as **almost risk-free securities** due to their AAA rating according to S&P. As a result, the **Austrian** Chamber of Public Accountants and Tax Consultants also recommends deriving the risk-free rate from the yield curve using the parameters published by the German Central Bank.¹⁾ Likewise, bonds issued by **Switzerland** enjoy a AAA rating and are also considered risk-free according to the Swiss National Bank.²⁾ Hence, a similar approach as for Germany and Austria is in our view appropriate for Switzerland with Swiss parameters.³⁾

To compute the risk-free rate for a specific reference date, the **Institute of Public Auditors** (Institut der Wirtschaftsprüfer, **IDW**) in Germany recommends using an **average value** deduced from the daily yield curves over the **past three months** (IDW S 1).

On the contrary, the Austrian Expert Opinion (KFS/BW 1) on company valuation recommends deriving the risk-free rate in line with the evaluated company's cash flow profile from the yield curve that is valid for the reference date (reference date principle). Thus, the KFS/BW 1 and its counterpart, the IDW S 1, differ from each other. Consequently, in the following analyses, we depict the yield curve for Germany following IDW S 1, while for Austria we adhere to the recommendations of KFS/BW 1.

For **Switzerland**, there is no generally accepted scheme to determine the risk-free rate. The most widely used risk-free rates in valuation practice are the yield of a **10-year Swiss government bond** as of the reference date as well as the **yield derived** from the 3-month average of the daily yield curves (in accordance with IDW S 1).

Additionally, we illustrate the monthly development of the risk-free rates since June 2017 for all three capital markets.

2. Interest rate calculated using the daily yield curve in accordance with KFS/BW 1 (no 3-month average).

Market returns and market risk premium *a. Implied returns (ex-ante analysis)*

Background & approach

Implied market returns and market risk premium

The **future-oriented** computation of **implied market returns** and **market risk** premiums is based on profit estimates for public companies and return calculations. This approach is called ex-ante analysis and allows us to calculate the "implied cost of capital". It is to be distinguished from the ex-post analysis.

Particularly, the ex-ante method offers an alternative to the ex-post approach of calculating the costs of capital by means of the regression analysis through the CAPM. The ex-ante analysis method seeks costs of capital which represent the return expectations of market participants. Moreover, it is supposed that the estimates of financial analysts reflect the expectations of the capital market.

The concept of **implied cost of capital** gained momentum recently. For example, it was recognized by the German Fachausschuss für Unternehmensbewertung "FAUB".1) It is acknowledged that implied costs of capital capture the current capital market situation and are thus able to reflect the effects of the current low interest rate environment.

Furthermore, recent court rulings with regards to appraisal proceedings appreciate the use of **implied cost of capital** as they are **forward-looking**. As of the **reference** date, it offers a more insightful perspective in comparison to the exclusive use of ex-post data.

For the following analysis, we use - simplified annually - the formula of the Residual Income Valuation Model by Babbel:2)

$$r_{t} = \frac{\mathrm{NI}_{t+1}}{\mathrm{MC}_{t}} + \left(1 - \frac{\mathrm{BV}_{t}}{\mathrm{MC}_{t}}\right) * \epsilon$$

1. cf. Castedello/Jonas/Schieszl/Lenckner, Die Marktrisikoprämie im Niedrigzinsumfeld – Hintergrund und Erläuterung der Empfehlung des FAUB (WPg, 13/2018, p. 806-825).

2. cf. Babbel, Challenging Stock Prices: Stock prices und implied growth expectations, in: Corporate Finance, N. 9, 2015, p. 316-323, 4. Approx. 75% of the total market capitalization (CDAX, WBI, SPI) is covered. in particular p. 319. In the observation period from H2 2020 until H2 2021, we applied t+2 earnings forecasts in our model due to distortions by the COVID-19 crisis;

With the following parameter definitions:

- r_{t} = Cost of equity at time t
- NI_{t+1} = Expected net income in the following time period t+1

MC_t = Market capitalization at time t

 BV_t = Book value of equity at time t

g = Projected growth rate

Through solving the models for the cost of capital, we obtain the implied return on equity.3) Since Babbel's model does not need any explicit assumptions, except for the growth rate, it turns out to be **robust**. We source all data (i.e. the expected annual net income, the market capitalizations, and the company's book value of equity, etc.) of the analyzed companies from the data supplier S&P Capital IQ. Additionally, we apply the European Central Bank target inflation rate of 2.0% as a typified growth rate.

Henceforth, we determine the **implied market returns** for the entire DAX, ATX and SMI. We consider these indices to be a valid approximation for the total markets.4) The results form the starting points for the calculations of the **implied market risk** premiums of the three capital markets. Subtracting the risk-free rate from the implied market returns results in the implied market risk premium.

To determine the appropriate market risk premium for valuation purposes, it is also important to take into account the analysis of historical returns as well as volatility. Especially in times of crisis it can make sense to apply an average market risk premium over several periods instead of a reference date value.

^{3.} cf. Reese, 2007, Estimation of the costs of capital for evaluation purposes; Aders/Aschauer/Dollinger, Die implizite Marktrisikoprämie am österreichischen Kapitalmarkt (RWZ, 6/2016, p. 195-202).

German, Austrian and Swiss markets

Implied market returns and market risk premium

Market returns and market risk premium *b. Historical returns (ex-post analysis)*

Background & approach

Historical market returns

Besides analyzing the implied market returns through the ex-ante analysis, we also analyze **historical (ex-post) returns**. Once this analysis is performed over a **long-term observation period**, an expected **return potential** of the German, Austrian and Swiss capital markets is assessable. Therefore, the analysis of historical returns can be used for **plausibility checks of the costs of capital**, more specifically **return requirements**, which were evaluated through the CAPM.

To further enable a precise analysis of the historical returns of the German, Austrian and Swiss capital markets, we use the so-called **return triangle**.¹⁾ It helps to present the **annually realized returns** from **different investment periods** in a simple and understandable way. Especially the **different buying and selling points in time** and the different annual holding periods are illustrated comprehensively. To calculate the **average annual returns** over several years, we use both the **geometric and arithmetic mean**.

In this study, we analyze the so-called **total shareholder returns**, which include the **returns on investments** and the **dividend yields**. For our analysis, it is crucial to focus on **total return indices** because they include the price and dividend yields. Since **DAX** is a performance index, we already have an index which includes the price and dividend yields. The ATX and SMI only include the price yields, hence we need their specific total return indices. The relevant total return index for Austria is called the **ATX Total Return** and for Switzerland **SMI Total Return**. The composition of both indices are identical to the ATX and the SMI and compromise 20 companies each.

The observation period amounts to 25 years. Therefore, the earliest data of the DAX and the ATX Total Return is from the end of 1997. However, the data of the SMI Total Return starts from the end of 1997. All ex-post returns are calculated using the data as of the reference date June 30, 2023.

The following slides illustrate how the two calculation methods (arithmetic and geometric) differ from each other for the period between June 30, 1998 and June 30, 2023:

- DAX:
 - the **arithmetic mean** of the historical market returns is **6.3%**
 - the **geometric mean** of the historical market returns is **4.2%**
- ATX:
 - the arithmetic mean of the historical market returns is 9.1%
 - the geometric mean of the historical market returns is 5.9%
- SMI:
 - the **arithmetic mean** of the historical market returns is **5.3%**
 - the **geometric mean** of the historical market returns is **4.2%**

1. The German Stock Institute e.V. (DAI) developed the return triangle for DAX and EURO STOXX.

Sector classification of the DACH region based on finexpert sector indices

Methodology & approach

finexpert sector indices of the DACH Region

The **finexpert** sector indices aim to cover the **whole capital market of the DACH region**. Therefore, this capital market study contains all equities of the German Composite DAX Index (CDAX), Vienna Stock Exchange Index (WBI) and Swiss Performance Index (SPI). These three indices contain all shares listed on the Official and Semi-Official Market.

The **629 public companies**, which are listed in the mentioned indices as of June 30, 2023, build the base for the **sector classification** and the **subsequent analyses**:

- The German DAX Sector All Index¹⁾ includes 368 companies listed in the Prime Standard and General Standard and is classified into nine "Deutsche Börse super sectors".
- The Austrian ATX only has five sector indices, ValueTrust assigns the remaining companies of the WBI to the classified sector indices.
- The Swiss SPI contains ten sector indices that comprise 204 companies.
 Eventually, <u>finexpert</u> merged all three market indices and the respective sector index classification into twelve <u>finexpert</u> sector indices, so-called "super sectors."

The twelve sector indices for this study are defined as follows:

- Banking
- Insurance
- Financial Services
- Consumer Service
- Consumer Goods
- Pharma & Healthcare

- Information Technology
- Telecommunication
- Utilities
- Basic Materials
- Industrials
- Real Estate

Complete sector classification of the DACH region in 12 sector indices

1. The DAX Sector All Index contains all equities listed in the Prime and General Standard as well as in the Scale segment of the Frankfurt stock exchange.

Sector distribution and number of companies

finexpert sector indices of the DACH Region As of June 30, 2023

Sector classification of the DACH Region

Banking (33)

Insurance (13)

- Financial Services (41)
- Consumer Service (51)
- Consumer Goods (74)
- Pharma & Healthcare (61)
- Information Technology (73)
- Telecommunication (12)
 - Utilities (13)
 - Basic Materials (36)
- Industrials (175)
- Real Estate (47)

- The chart shows the percentage distribution of the 629 listed companies in the twelve "super sectors" (the absolute number of companies is displayed in parentheses).
- The twelve defined sectors can be classified in three different dimensions:
 - eight different sectors represent a proportion of less than 10%,
 - three represent a share between 10% and 20%,
 - and only one represents a portion of more than 20%.
- Companies within the Industrials, Information Technology and Consumer Goods sectors, hence, represent approximately half of the entire market.

1. Including asset managers, leasing firms and distribution companies for financial products.

Background & approach

Betas

Beta is used in the **CAPM** and is also known as the beta coefficient or beta factor. Beta is a measure of **systematic risk** of a security of a specific company (**company beta**) or a specific sector (**sector beta**) in comparison to the market. A beta of less than 1 means that the security is theoretically less **volatile** than the market. A beta of greater than 1 indicates that the security's price is more volatile than the market.

Beta factors are estimated based on historical returns of securities in comparison to an approximate market portfolio. Since the company valuation is forward-looking, it has to be examined whether or what potential risk factors prevailing in the past also apply for the future. By valuing non-listed companies or companies without meaningful share price performance, it is common to use a beta factor from a group of comparable companies ("peer group beta"), a suitable sector ("sector beta") or one single listed company in the capital market with a similar business model and a similar risk profile ("pure play beta"). Within this capital market study we have used sector betas which are computed as arithmetic means of the statistically significant beta factors of all companies of a particular sector.

The estimation of beta factors is usually accomplished through a **linear regression analysis**. We use the CDAX, WBI, and SPI as country specific reference indices.

Furthermore, it is important to set a time period for which the data is collected (**benchmark period**) and whether daily, weekly or monthly returns (**return interval**) are analyzed. In practice, it is common to use **observation periods of two years** with the regression of **weekly returns** or a **five-year observation period** with the regression of **monthly returns**. Both alternatives are displayed in our study.

In the CAPM, company specific **risk premiums** include not only **business** risk, but also financial **risk**. The beta factor for levered companies ("**levered beta**") is usually higher compared to a company with an identical business model but without debt (due to financial risk). Hence, **changes in the capital structure** require an **adjustment of the betas** and therefore of the company specific risk premiums.

In order to calculate the **unlevered beta**, adjustment formulas have been developed. We prefer to use the **adjustment formula by Harris/Pringle** which assumes a value-based financing policy, stock-flow adjustments without time delay, uncertain tax shields and a so-called **debt beta**. We calculate the debt beta based on the respective company's rating or the average sector rating (if a company's rating is not available) through the application of the **credit spread** derived from the expected cost of debt. We do not adjust the credit spread for unsystematic risks. The capital market data, in particular historical market prices, is provided by the data supplier S&P Capital IQ.

Sector specific levered and unlevered betas as of June 30, 2023 (arithmetic mean) Betas

2-years weekly (darker t	fill) 5-years n	nonthly (transparent fill)
Sector	Beta levered	Beta unlevered
Banking ¹⁾	0.80 0.93	n.a.
Insurance 1)	0.95 0.75	n.a.
Financial Services 1)	1.07 1.02	n.a.
Consumer Services	1.05 0.97	0.88 0.83
Consumer Goods	1.13 0.91	0.78 0.68
Pharma & Healthcare	1.03 1.03	0.94 0.94

1. We refrained from adjustments of the companies' specific 2. For all DACH companies, the market value-weighted mean of debt (unlevered) because indebtedness is part of the companies' operational activities and economic risk. Bank specific regulations about the minimum capital within financial institutions let us assume that the indebtedness degree is widely comparable. For that reason, it is possible to renounce the adaptation of levered betas.

the levered beta was calculated. This value deviates slightly from 1 due to the exclusion of statistically insignificant betas.

Sector	Beta levered	Beta unlevered
Information technology	0.97	0.99
W Telecommunication	0.73 0.55	0.62
Utilities	0.73	0.55 0.57
Basic Materials	1.11 0.98	0.80 0.71
Industrials	1.25 1.09	0.98 0.89
Real Estate	0.82	0.54
DACH ²⁾	1.02 1.02	

VALUETRUST a brand of PVT Financial Advisors SE

Sector returns a. Implied returns (ex-ante analysis)

Background & approach

Implied sector returns

Other than the future-oriented calculation of **implied market returns** (cf. slide 16 et seq.), we calculate **implied returns for sectors**. That offers an **alternative** to and simplification of the **ex-post analysis** of the company's costs of capital via the **CAPM**. Using this approach, the calculation of sector betas via regression analyses is not necessary.

The **implied sector returns** shown on the following slides can be used as an **indicator** for the **sector specific levered costs of equity**. Those already consider **sector specific leverage**. Accordingly, another simplification would be to renounce making adjustments with regards to the capital structure risk.

Comparable to the calculation of the implied market returns, the following return calculations are based on the Residual Income Valuation Model by *Babbel*.¹⁾ The required data (i.e. net income, market capitalization, and book values of equity) are sourced from the data provider S&P Capital IQ. With regards to the profit growth, we assume a growth rate of 2.0%.

We unlever the implied returns with the following **adjusting equation** for the **costs of equity**²⁾ to take the specific leverage into account:³⁾

$$\mathbf{r}_{\mathrm{E}}^{\mathrm{L}} = \mathbf{r}_{\mathrm{E}}^{\mathrm{U}} + \left(\mathbf{r}_{\mathrm{E}}^{\mathrm{U}} - \mathbf{R}_{\mathrm{f}}\right) * \frac{\mathrm{D}}{\mathrm{E}}$$

with:

 r_E^L = Levered cost of equity r_E^U = Unlevered cost of equity R_f = Risk-free rate $\frac{D}{E}$ = Debt⁴⁾-to-equity ratio

The **implied unlevered sector returns** serve as an indicator for an **aggregated** and **unlevered cost of equity** for **specific sectors**. The process of relevering a company's cost of capital to reflect a company specific debt situation (cf. calculation example on the next slide) can be worked out without using the CAPM.

- cf. Babbel, Challenging Stock Prices: Share prices and implied growth expectations (Corporate Finance, n. 9, 2015, p. 316-323, especially p. 319); cf. Aders/Aschauer/Dollinger, Die implizite Marktrisikoprämie am österreichischen Kapitalmarkt (RWZ, 6/2016, p. 195-202).
- 2. In situations in which the debt betas in the market are distorted, we would have to adjust these betas to avoid unsystematic risks. For simplification reasons, we deviate from our typical analysis strategy to achieve the enterprise value (Debt beta > 0) and assume that the costs of debt are at the level of the risk-free rate. This process is designed by the so-called Practitioners formula (uncertain tax shields, debt beta = 0), cf. Pratt/Grabowski, Cost of Capital, 5th ed., 2014, p. 253.

3. We assume that the cash and cash equivalents are used entirely for operational purposes. Consequently, we do not deduct excess cash from the debt.

p. 195-202).
 a. "Debt" is defined as all interest-bearing liabilities. The debt illustration of the companies in the Banking, Insurance and Financial
 b. In situations in which the debt betas in the market are distorted, we would have to adjust these betas to avoid unsystematic risks.
 b. Services sector only serves an informational purpose. We will not implement an adjustment to these companies' specific debt (unlevered) because their indebtedness is part of their operational activities and economic risk.

Exemplary calculation to adjust for the company specific capital structure

Implied sector returns

Calculation example:

As of the reference date June 30, 2023, we observe a sector specific, unlevered cost of equity of **6.9%** (market-value weighted mean) in the German Basic Materials sector. For the exemplary company X, which operates in the German Basic Materials sector, the following assumptions have been made:

- The debt-to-equity ratio of the exemplary company X: 40%
- The risk-free rate: 2.43% (cf. slide 13)

Based on these numbers, we calculate the relevered costs of equity of company X with the adjustment formula:

 $r_{\rm E}^{\rm L} = 6.9\%$ + (6.9% - 2.43%) * 40% = 8.7%

Thus, **8.7%** is the company's relevered cost of equity. In comparison, the levered cost of equity of the Basic Materials sector is **10.0%**, reflecting the sectors' higher average leverage.

Overview as of June 30, 2023 vs. December 31, 2022

Implied sector returns Unlevered ¹⁾

1. The returns for the sectors Banking, Insurance and Financial Services are levered sector returns. For all other sectors unlevered returns are displayed.

Sector returns b. Historical returns (ex-post analysis)

Background & approach

Historical sector returns

In addition to the computation of historical market returns, we calculate historical sector returns. This allows for an alternative approach, like the implied sector returns, to the ex-post analysis of the determination of costs of capital based on regression analyses following the CAPM.

Our analysis contains so-called **total shareholder returns** analogous to the return triangles for the German, Austrian and Swiss total return indices. This means, we consider the **share price development** as well as the **dividend yield**, whereas the share price development generally represents the main component of the total shareholder return.

We calculate the **annual total shareholder returns as of June 30**, for every DAX Sector All Index, WBI, and SPI listed company. Afterwards, we aggregate those returns market-value weighted **to sector returns**. Our calculations comprise the time period between 2018 and 2023. Since annual total shareholder returns tend to fluctuate to a great extent, their explanatory power is limited. Therefore, we do not only calculate the 1-year market-value weighted means, but furthermore calculate the 3-year (2021-2023) and the 6-year (2018-2023) averages.

Background & approach

Historical sector returns

-2.4%

Background & approach

Trading multiples

Besides absolute valuation models (earnings value, DCF), the **multiples approach** offers a practical approach for an enterprise value estimation. The multiples method estimates a company's value **relative** to another company's value. Following this method, the enterprise value arises from the product of a reference value (revenue or earnings values are frequently used) of the company with the respective multiples of **similar companies**.

Within this capital market study, we analyze **multiples for the "super -sectors"** as well as **multiples for the DACH market** consisting of the German, Austrian and Swiss capital markets (DAX Sector All Index, ATX and SPI). We will look at the following multiples:

- Revenue-Multiples ("EV¹/Revenue")
- EBIT-Multiples ("EV¹/EBIT")
- Price-to-Earnings-Multiples ("P/E")
- Price-to-Book Value-Multiples ("EqV²/BV")

Multiples are presented for the reference dates June 30, 2023 and December 31, 2022. The reference values are based on one-year forecasts of analysts (so called forward multiples, in the following **"1yf"**). Solely the Price-to-Book-Value-Multiples are calculated with book values as of the reference dates. We present **median** values.

We present historical multiples as of June 30, 2017 in the appendix and will update the applied multiples semi-annually at the predefined reference date (as of December 31 and as of June 30).

For the purpose of **simplification**, we exclude negative multiples and multiples in the highest quantile (95%). The multiples in the lowest quantile (5%) build the lower limit.

To calculate the multiples, we source the data (i.e. Market Cap., Revenue, EBIT, etc.) from the data provider S&P Capital IQ. Based on the availability of data, especially in terms of forecasts, the number of companies underlying each specific multiple varies.

Additionally, we present a **ranking table** of the sector multiples. Firstly, sector multiples are sorted from highest to lowest for each analyzed multiple. The resulting score in the ranking is displayed in the table and visualized by a color code that assigns a **red color** to the **highest rank** and a dark **green color** to the **lowest rank**. Thus, a red colored high rank indicates a high valuation level, whereas a green colored low rank suggests a low valuation level. Secondly, we aggregate the rankings and calculate an average of all single rankings for each sector multiple. This is shown in the right column of the ranking table. This **average ranking** indicates the overall **relative valuation levels** of the sectors when using multiples.
